*This paper presents an educational experience developed in the forth year of Computer Engineering degree at Huelva University (Spain). To make more captivating Artificial Intelligent (AI) learning processes, a new educational project was incorporated into classical teaching of Artificial Intelligence and Knowledge Engineering subject. In this paper, we present the experience fulfilled with a group of college students. Here it is related how they changed for some days their classroom lessons by the robotic competition arena. With this project we have extended regular classroom lessons with additional work that would be useful and may not be provided by traditional practical lessons, the real life experience. As real example about how the work was accomplished we describe the mechanical construction of the mobile robots as well as the software development process.*

**Keywords:** artificial intelligence; engineering education; gaming; robotics

---

## INTRODUCTION

THIS PROJECT was a perfect example to make students gain some interest on robotics and robotic competitions are a good framework to develop classroom experiences. Competitions also offer to the students the opportunity of meeting people more experienced on their field. It also helps students to realize that frequently, real life is different from the problems the students solve at the university. It is completely different to design or program code for a computer simulation that to do it for a real mobile robot. For example, there are many factors that have to be taken into consideration, like the mobile robot's battery charge or the light at the competition hall. In our case, it gave us some valuable pieces of advice; some of them about hardware design and others about how to design our software.

The competition game consisted of developing a mobile robot able to follow a line as fast as possible in a simple track. But, which is the significance of these terms?

- “A robot is a virtual or mechanical agent. In practice, it is usually an electromechanical system which, by its appearance or motion, conveys a sense that it realizes by its own”.
- “A robotic competition is an event where robots have to accomplish a given task”.

These two definitions —given by Wikipedia— describe the concepts of a robotic competition. A robotic contest is important for AI because two robots with no human help or guidance have to fulfill a given task faster or better than the rest of the competitors. In general terms, in a basic AI lab practice, it is enough if the robot accomplishes the task; no

matter how much time it takes to do it. In a robotic competition it is not enough, the behavior of the robots must also be changed and improved so it can beat the rest of the competitors.

There are many already developed robotic platforms as Pololu, e-puck [1] or Khepera [2] but we have developed the complete platform and control software for this hardware. So, students have developed new skills designing and building Printed Circuit Boards (PCBs), working with electronic components or designing embedded software. Almost all the technical teaching have the goal to form tomorrow's engineers and this experience brings class closer to real-life frameworks. As example, in Zhongli et al. [3] is presented an Internet-based platform for a soccer competition devoted to robotics education. To facilitate learning of the students participating in the robotics competition, the supporting hardware and software kits have been also developed. DeVault [4] describes an engineering experience through the implementation of a mobile robotics course and the participation in an annual robot contest. In Grimes et al. [5] are described the educational outcomes and student know-how that make a competition an excellent opportunity for student educational growth. In this paper is illustrated how the students have full responsibility for defining the competition rules, designing, constructing the course and carrying out the competition. In Berlier et al. [6] is presented a methodology used to replace the final project with a robotics project where students built a microcontroller-based robot with the ultimate goal of competing. Murphy [7] describes a strategy for integrating robot design competitions into courses in order to maximize learning experience and promote intellectual development. Finally, in Almeida et al.

[8] mobile robot competitions are presented as events well suited to experimentation, research and development in many areas concerned both High School and University.

The present paper is organized in the following way. The “General Overview” section presents the ‘OnuBot’ teamwork and how the motivation to compete comes from the classroom to mobile robots competition arena. The following section “Project Development” explains the task development and how the work was accomplished. The “Competition” section briefly discusses the results of this game. The “Experience in Teaching” section puts into practice the methodology developed by this teamwork so far, an evaluation questionnaire is presented with such purpose. Finally, this paper contributes some conclusions on the work carried out, provides new expectations and offers this experience to the engineering community at its social website.

In order to clearly highlight the contributions of this teaching innovation project, different features and properties are compared with some of the aforementioned educational experiences (see Table I).

## GENERAL OVERVIEW

We have used mobile robots during the last five years as a means of teaching main mobile agents aspects. In the firsts years students showed an excellent motivation. Nevertheless, this interest has gradually decreased in the subsequent years. These students were doing the forth year of ‘Computer Engineering’ degree at Huelva University and this project was developed in the ‘Artificial Intelligence and Knowledge Engineering’ subject.

The experience started in the academic course 2008/2009 and was mostly participated by students. This experience allows us to obtain a teaching innovation project awarded by the University of Huelva. This project permitted to the teachers setting up two different students’ teams and two different mobile agents —Mini-Z and Iwaver 01— with the goal of participating in a national robotic competition called ‘Cosmobot 2009’ (see Fig. 1). The competition was participated by 24 teams from different national universities. The game consisted of developing two mobile robots able to follow a line as fast as possible in a simple closed track.

This collaborative experience is not only understood as a serial of practical sessions. Otherwise it comprises the possibility of discovering AI techniques with the aim of a robotic competition. In this project we have extended regular classroom lessons with additional work that would be useful and may not be provided by many traditional practical lessons. Such tasks — approximately 600 hours— consisted in working with electronic components, develop PCBs, designing embedded software, modeling the systems using Unified Model Language (UML) diagrams or testing AI algorithms (see Table II). So, working in group has also been important to accomplish the project.

Fig. 1. The Onubot teamwork in the competition arena during Cosmobot.

TABLE I  
MAIN FEATURES OF SOME EDUCATIONAL EXPERIENCES ON ROBOTIC COMPETITIONS

| Reference | Education Level          | Kind of Competition                       | Programming Language    | Field                                   |

## PROJECT DEVELOPMENT

### Rules of the Competition

The first task we had to do, once the working team had been formed, was to study the rules of the competition which had been previously published at the ‘Cosmobot 2009’ official website. This information included all the requirements to fulfill by the participants and their robots. To sum up, the most relevant aspects were the following:

- Every team should be formed by four members with one representative.
- Every team could have more than one mobile robot.
- The track was closed, white and delimited in both sides by black insulating tape lines of 2 cm wide. The whole track was 1550 cm wide. At the same time, there was a margin of 15 cm in each side delimited by a red insulating tape.

- The mobile robot should not ever reach those lines in its routes because it would be disqualified.
- The bends were made of pieces of circumference whose radius was always over 40 cm.

In addition, there were some possible eventualities contemplated as, for example, the fact that the track had little irregularities or that the lighting condition where not defined beforehand. Finally, it is important to point out the limitations imposed on the vehicles. They must have a maximum dimension of 20 cm wide x 30 cm long x 13 cm high, apart from being completely autonomous. It was completely forbidden the existence of any remote control element.

#### *Brainstorm Meetings*

Once all the rules of the competition where known, we met in order to prepare the work to develop. On the one hand, the leader suggested to the teamwork the strategy of buying two specific mobile robots which had a reduced size and low cost. On the other hand, we had to make our own PCBs where insert the chosen microcontroller, sensors and other electronic devices. Once the PCBs had been made it would be joined to the chassis of the vehicles and the appropriate connections would be done.

The robotic vehicles —Mini-z and Iwaver 01— both had very similar qualities and their dimensions where approximately 12 cm long x 7 cm wide x 4 cm high (see Fig. 2). The chosen microcontroller was Javelin Stamp™ from Parallax enterprise (see Fig. 3). This election was due to the fact that we were already familiar with the use of this microcontroller in the practices of ‘Artificial Intelligence and Knowledge Engineering’ subject. In these practices we got in touch with the robots programming and with external elements interaction. During the first meeting of the teamwork we considered the possibility of using the Parallax version of CMUcam camera as complement of the car. The rules allowed it and, at the beginning, we thought that it would be useful to give a computer vision feedback to the vehicle. We guessed that the robotic vehicles could see the bend before arriving and react with more efficiency. Finally, this option was ruled out because of several reasons. First, the camera’s weight decreased speed and stability of the vehicle as well as its autonomy. Second, the processing capacity required by this camera and the microcontroller became inadequate.

Inspired by the mobile robots used in our practices, we decided to include two sensors in the central part at the front of the vehicle. Also we established that the vehicle would go over the line, although it was allowed to cover the white track space. We left the possibility to add two extra sensors, one in each extreme of the front side.

#### *PCB Layout and Assembling Process*

Once the working process became clear, we started to meet again during the following days, this time in order to make the PCB design by means of EAGLE Layout Editor®. The electronic circuit was already designed so we printed it in

TABLE II  
LIST OF TASKS AND HOURS SPENT ON THE PROJECT

| Item | Hours | Persons | Task   |
|------|-------|---------|--|
| 1    | 2     | All     | Briefing & work organization   |
| 2    | 3     | 6       | Working with robot: task planning, interfaces, programming & debugging       |
| 3    | 3.5   | 3       | Working with robot: track design & reactive algorithm                        |
| 4    | 4.5   | 5       | Schematic & layout design with Eagle   |
| 5    | 4     | 1       | Mapping & testing track algorithm  |
| 6    | 3     | 6       | Printing board, develop & etching  |
| 7    | 4.5   | 2       | Reactive algorithm & adjust parameters                                       |
| 8    | 3     | 2       | Welding, drilling & assembling PCB   |
| 9    | 2     | 3       | Reactive algorithm & optimization for straight lines                         |
| 10   | 2     | 1       | Working with robot: testing algorithm in circuit with predominance of curves |
| 11   | 5     | 2       | Testing with robot: creation of new circuits & parameter settings            |
| 12   | 6     | 1       | Working with 2nd robot: assembly, testing & new servomotors                  |
| 13   | 2     | 2       | Research on CMUcam   |
| 14   | 5     | 4       | UML design: tasks & processes to perform                                     |
| 15   | 3     | 1       | UML specification: classes, attributes & methods                             |
| 16   | 9     | All     | Code debugging and circuit preparation                                       |
| 17   | 12    | 4       | Improving code   |
| 18   | 3     | 3       | Algorithm advances with Iwaver & Mini-Z robotic vehicles                     |
| 18   | 40    | All     | Cosmobot 2009 competition  |
| 20   | 10    | 2       | Updating webpage   |
| 21   | 6.5   | 1       | Microcontroller research   |
| 22   | 4.5   | 1       | Documentation of the directed academic work                                  |

transparencies. Taking advantages of the University’s facilities we could use a laboratory to make the PCBs. The process had the following steps:

- Designing and cutting the light photosensitive bakelite with the intended size.
- Sticking tightly, by means of sticky tape, the piece of the PCB and the printed sheet. After this, putting them into the isolation machine. This machine is like a photocopier with a special light and, in fact, it carries out a similar function applying an ultraviolet light to the whole PCB. The light intensity excites the PCB’s surfaces except the drawn mask that will be the copper traces of the future circuit.
- When it becomes photosensitive, the board was carefully introduced into a photo-sensitive dissolution of a specific product to reveal it.
- Etching all the photosensitive PCB area leaving only the fiberglass base with the printed circuit intact.

The assembly of the hardware was the following task. Once we already had the PCBs, we only had to drill, sold and assemble the set of resistances, capacitors and undoubtedly the microcontroller.

#### *Software Specification and Requirements*

Due to the short time available to build and program the robots, it was necessary to distribute the different task between the people in the project, so we could finish on time. To

achieve this goal we modeled the system using UML diagrams.

We decided to clarify the way to develop the desired work in a common and efficient way. In that sense, we had to carry out a detailed analysis of all the existing variables related with the competition. Accordingly, the variables were classified taking into account if they were related to the robotic vehicle or the track. These variables are shown in Table III. Can be observed that, light intensity, affects to the measurement of the sensors. By other hand, when the battery charge got low, the speed and acceleration got down. Respect to the speed, we had to decide if put the cars at high speed or medium speed. With high speed, the cars sometimes went off the road so we had to decide what level of risk we should accept. It also was important to know if the cars were in a curve or in a straight line because the turning angle to correct the car should be different. Under our experience, the number of sensors was an important lack of our robotic vehicles since they only had two sensors. We discovered that it could not have enough accuracy; even so, it was enough for our design. It was also very important to know other physical limitations like size of the wheels, position of axis direction, weight, stability and specially the hit resistance. According to the variables related with the track of the competition arena, stretches position maybe the most important variable. We programmed the car with a map of the circuit so it could always be in the best position and anticipate the next event before it comes. With this, we expected the car braked before the curve and accelerated when the straight line was beginning. About friction, was important to know that the results obtained in our tests could differ significantly from the results obtained in the official circuit due to material construction. Another aspect terribly important was the pothole. Both, our test circuits and the official one contained undulations. These strains were mainly caused by the tension of the tape that formed the path. Our small robotic cars were negatively influenced by it.

We concluded that if we knew the features of the track, we could set a clear analysis and the mobile robot could react before. By means of that, we could do diagrams about the program structure in UML format. Besides, it would be necessary to program every section of the track in a single way, so that we could finally combine all of them. Thus, we realized that students required an additional effort to provide a high reliability to the design of mobile agents. Usually this aspect is not crucial for general purpose software developed on AI. That is, when something wrong happens the computer engineer usually shows “windows alerts”. On the contrary, in a competition a fault means the end of the game for competitors; no faults or errors are allowed. Certainly, this aspect is difficult to learn out of a real problem.

#### *Firsts Tests at the Laboratory*

The program was developed in Java language but avoiding the use of classes and minimizing the calls to external functions to reduce the computational cost (see Fig. 4). We realized that we based our strategy in a good software design, but our basic hardware did not let us make a working program

Fig. 2. Iwaver 01 robot of the Onubot teamwork in the competition arena during Cosmobot.

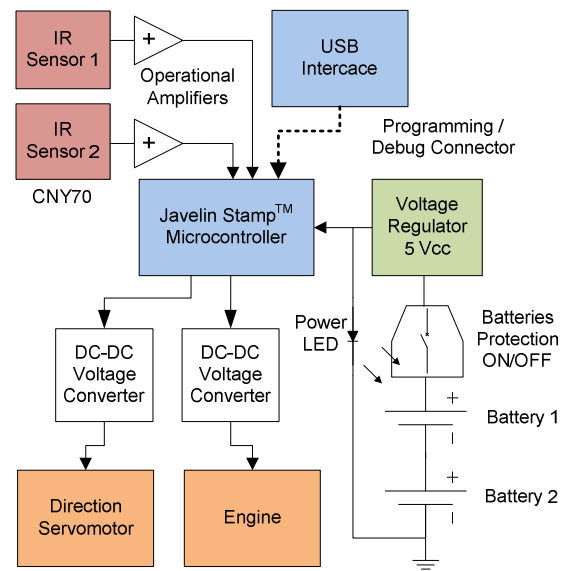

Fig. 3. Outline of the electronic aboard the robotic vehicles.

TABLE III  
CLASSIFICATION OF VARIABLES RELATED WITH THE MOBILE ROBOTS AND THE TRACK OF THE COMPETITION ARENA

| Variables          | Related with                            |
|--------------------|---|
| Light intensity    | Sensor measurements                     |
| Battery charge     | Speed & acceleration                    |
| Maximum speed      | Risk level                              |
| Turning angle      | Motion in a curve or in a straight line |
| Number of sensors  | Accuracy                                |
| Physical limits    | Behavior of the robotic vehicle         |
| Stretches position | Anticipation to the next event          |
| Friction           | Behavior of the robotic vehicle         |
| Pothole            | Disorientation                          |

that could satisfy the competition requirements. It was difficult to fulfill the task with our designed hardware, because we designed a simple and fast system with only two light sensors with digital signal processing. When we tried to make a high

speed control with only two sensors, we comprehended that environmental light conditions and circuit surface would cause wrong measurements. Thus, at high speeds these fails cause to the mobile robots loosing the line and going out from the circuit. Consequently, the team will be withdrawn from the competition.

In the following stage, we thought it would be a good idea to make a copy of the competition track, so we started working on that. One of the problems consisted on the material to support the track; getting a plastic sheet was too expensive. As consequence, we used a great toll of paper as base. To do this, we firstly added several sheets in order to get the desired dimensions. Secondly, by means of a tape, we composed the straight lines and the curves all the way long. We already had our track; thanks to it we could perform our first reliable test.

At that moment we could see the true necessity to improve the speed and the efficiency of the robotic vehicle. Moreover, we could face the problem of the distortions on the track beforehand. These were mainly caused by the tension produced, not only by the insulating tape but also by the paper fragility. This situation would be reflected on the true track. That is the reason why all participants have the same problems like us.

The software development continued but it did not live up to our expectation. We understood the necessity of having more sensors for a better accuracy measurement that would influence the behavior with more precision. In addition, we had difficulties with the batteries, so the battery overuse by the car's engines negatively influenced on acceleration and braking cycles. These and other reasons made us decide to load a more primitive algorithm into the robot only few days before the competition. This algorithm did not perform complicated intelligent analysis; it simply reads the sensors, being the engine speeds and servomotors' direction constant. The result was not very fast but at least it did not come off the bends and allowed a higher working autonomy. In Figure 5 can be seen these tests realized with algorithms tuned at different speeds. The lines show distance traveled by the robotic vehicle (expressed in cm) versus time (represented in seconds).

## COMPETITION

We went to 'Cosmobot 2009' with the proof material including our track. We were surprised due to the fact that any participant did not carry anything similar and they only had little stretches over different surfaces to calibrate the sensors' sensibility. This made us reflect upon the greater importance of pure mechanics and electronics versus the computer analysis we mainly had done. All competitors tried out their vehicles in our track and we apprehended the invested effort had been worthy: most vehicles came off or made maneuvers that would make them fail. We could notice some similar models of robotic vehicles like our ones with very specialized features prepared for this competition. As we could check later these competitors keep on participating with all their vehicles.

```
// */
public static void wait_start(){
    System.out.println("pass1");
    while(CPU.readPin(SWICTH) != ON){}
    System.out.println("pass2");
    while(CPU.readPin(SWICTH) == ON){}
    System.out.println("pass3");
}

public static void main (){

    int MAXIMUM_TURN = GREAT_TURN[2];
    int MINIMUM_TURN = LITTLE_TURN[0];
    int MAXIMUM_SPEED = HIGH_SPEED[1];
    int MINIMUM_SPEED = LOW_SPEED[1];
    int direction=1; //1 right, -1 left
    int speed = MINIMUM_SPEED;
    int turn = 0;

    // wait_start();

    CPU.writePin(LED1,true);
    CPU.writePin(LED2,true);
    while(true){
        servo_mot.update(neutral_engine+speed, low_mot);
        servo_dir.update(neutral_direction + (turn * direction), low_dir);

        if (CPU.readPin(SID) == INSIDE && CPU.readPin(SDD) == INSIDE){
            speed = HIGH_SPEED;
            turn = 0;

        }else if(CPU.readPin(SID) == INSIDE && CPU.readPin(SDD) == OUTSIDE){
            turn = MINIMUM_TURN;
            direction = 1;

        }else if(CPU.readPin(SID) == OUTSIDE && CPU.readPin(SDD) == INSIDE){
            turn = MINIMUM_TURN;
            direction = -1;

        }else if(CPU.readPin(SID) == OUTSIDE && CPU.readPin(SDD) == OUTSIDE){
            turn = MAXIMUM_TURN;
            speed = MINIMUM_SPEED;
        }
    }
}
```

The competition took place in a very short time and in a very good sporting atmosphere. Its dynamics was also specified in the rules. It would consist of a first validation lap in which all the robot vehicles had to prove their capacity to cover the track without coming of or time limit. Later, each vehicle performed individually a round of three tries. The goal was to complete at least two laps in the shortest time possible. Once all the vehicles attained the classification, approximately half of them passed to the following step: the car chase. In this step, two vehicles placed in opposite points of the track started at the same time. The race finished when one of the two mobile robots reached the other and the winner was the one which had it done twice in at least two big tries.

We did not have any problem at passing the validation lap and later the classification, but the quality of our opponents exceeded our robotic systems. Our teams took 41.87s to make 2 laps with an average speed of 0.54 m/s. The best competitor took 14.93 s to make the same laps with an average speed of 1.52 m/s, taking 102.60 s the worst runner with an average speed of 0.22 m/s. This made us finish in a middle position. When the competition finished the winners where congratulated and agreed to be interviewed by us. It was very interesting sharing experiences with different competitors who kindly explained the bases of their designs. The experience has been quite pleasant and we consider that in this first attempt we have learnt a lot of things about working in group, especially when this work is orientated towards a competition task.

## EXPERIENCE IN TEACHING

With the aim of addressing innovative teaching and learning methods related with this experience, we have evaluated the students' opinion and its implications for Engineering

Education. A statistical study have been carried out on two teamwork of students and teachers during the 2009 year (see Table IV) with a score ranging between 1 (completely disagree) and 5 (completely agree). The questionnaire includes aspects referred to how the educational gaming has improved teaching-learning practices in university education. Two groups of users (6 students and 2 professionals) have been considered.

Questions 1 to 11 describe the level of knowledge acquired on several technical fields like electronics, sensors and microcontrollers as well as transverse knowledge like project management, software programming, and modeling, designing and developing of systems (see fig. 6a). In these items can be observed that students' rates are higher with those questions related with hardware development (questions 1, 6 and 7) and lower with those ones related with software programming (questions 3, 6 and 8). The low rate in question 8 indicates that students already have a thorough knowledge of programming languages when they get to fourth course in Computer Engineering. By other hand, question 10 proves that AI knowledge has been strengthened.

Figure 6b shows how the students' opinion is in line with the opinion of teachers. Most of questions favorably scored are they related with the competition working and the social development of the person (question 12). Perhaps, the most important interpretation is that questions 19 and 20 stand out the motivation and its implications for both 'Artificial Intelligent' subject and robotic agents. In this sense, students and teachers highlight the success of the competition experience being rather high (questions 18, 21 and 22). It is still too early to obtain concluding results; although the developed analysis leads the professionals to conclude that with the educational experience we obtained several additional

targets that helped students to develop their skills. In general terms, it has been a great learning experience, we have learned from the difficulties and even when the result were not the expected ones, all the acquired knowledge is perfectly worth.

## CONCLUSIONS

Student motivation is an essential issue in a learning process and it implies challenge for educators who want to preserve and increase this educational aspect. We have used mobile robots during the last five years as a means of teaching mainly mobile agents aspects. In the firsts years students showed excellent motivation. Nevertheless, this interest has gradually decreased in the subsequent years. In order to make more captivating the AI learning process, we decided to incorporate a new practical session. That session comprises the possibility to put in common discovered AI techniques in a robotic competition. In this paper, we present the experience fulfilled with a group of students at university where they changed for some days their classroom lessons by the robotic competition arena. We describe the mobiles robots construction and software development process including modeling, design, and implementation and testing phases.

We concluded that participating in robotics competitions gives to university students a broader vision of AI subject, extra motivation and the possibility to share knowledge with more experienced students belonging to other universities. In order to evaluate the teamwork's activities, we present a pedagogical survey that emphasizes the importance of working in group with a real robot designed for a competition. Our experience will always be a good start point to develop a similar project with future promotions. Furthermore, the positive experience had bring up so much expectatives that teachers and students have confirmed to compete this year again. Besides, the students evidence the intention to accomplish future works in AI mobile agents' domain. Videos, links and further information about this work are available at the Onubot teamwork's site: [www.facebook.com/pages/Onubot/103904463217](http://www.facebook.com/pages/Onubot/103904463217).
